

Applying Shaders to a Sprite

Write custom GLSL code that modifies the look of your sprite.

Overview

You can use the `shader` property of a sprite node to change the appearance of a texture with a custom OpenGL ES fragment shader embedded within a `SKShader` object. Custom shaders offer almost limitless possibilities, from adding blurs and color treatments to textures to generating imagery such as random noise.

The following code shows a small custom shader which inverts the color of a texture while leaving the alpha or transparency unaffected:

```
let negativeShader = SKShader(source: "void main() { " +  
    "    gl_FragColor = vec4(1.0 - SKDefaultShading().rgb, SKDefaultShading().a); "  
+  
    "}")  
rocket.shader = negativeShader
```

The following figure illustrates the effect of the shader. The original image, on the left, has its colors inverted by the shader:
